In physics and fluid mechanics, a boundary layer is the layer of fluid in the immediate vicinity of a bounding surface where the effects of viscosity are significant. In the Earth's atmosphere, the atmospheric boundary layer is the air layer near the ground affected by diurnal heat, moisture, or momentum transfer to or from the surface. On an aircraft wing the boundary layer is the part of the flow close to the wing, where viscous forces distort the surrounding non-viscous flow.

Convection boundary condition is probably the most common boundary condition encountered in practice since most heat transfer surfaces are exposed to a convective environment at specified parameters. In other words, this condition assumes that the heat conduction at the surface of the material is equal to the heat convection at the surface in the same direction.

The region in which flow adjusts from zero velocity at the wall to a maximum in the main stream of the flow is termed the boundary layer. The concept of boundary layers is of importance in all of viscous fluid dynamics and also in the theory of heat transfer. mentioned system of equations. The essence of the boundary layer method is as follows. In external flow past the body surface, by convention it is possible to select two regions: the region near the surface in which the action of viscosity and heat conduction (boundary layer) much manifests itself and the external flow region (far from the

The transfer of heat between a solid boundary and a fluid takes place by a combination of conduction and mass transport. If the boundary is at a higher temperature than the fluid, heat flows first by conduction from the solid to fluid particles in the neighborhood of the wall. The energy
